

# Full State Pose Estimation Using a Satellite Imager

by

D.P. Theron

*Dissertation presented for the degree of Masters of  
(Electronic Engineering) in the Faculty of Engineering at  
Stellenbosch University*

Supervisor: Prof. H.W. Jordaan

2025

*To God, my Wife and my Mother*

---

# ACKNOWLEDGEMENTS

---

- \* Prof. H.W. Jordaan, thank you for all your patience and guidance through this journey.
- \* Pinkmatter for your financial support for taking the risk of investing in me and my future. I will be eternally grateful. Thank you for letting me feel like part of the company and taking such good care of me during the visits.
- \* Clarissa, my wife, thank you for all your love and support during the difficult times.
- \* My Mother, words cannot describe how much you meant to me during my masters degree.
- \* My friend and colleagues in the ESL, especially Brandon Chetty, Dane Groves and Mark Msonko, who put up with my 'new productivity hacks' and 'crazy ideas', but also keeping me on track.
- \* God, for all your guidance, support, love and faith in me, even though I didn't deserve it.

*“ Above all else remember the friends you made along the way,  
because it is not your journey that defines you, it is the people you help  
and help you along the way. ”*

– Mr. Niel Theron

# ABSTRACT

---

Pose estimation on nanosatellites is still an on going topic of interest. It is important for satellite to know there position and attitude to do accurate target tracking. Traditional solutions to the pose estimation problem is mainly star trackers, which looks at the constalations of stars to determine the attitude and GPS to determine the position of the satellite along with other sensors like magnetometers and coarse sun sensors.

In this thesis, a sensor is developed that utilises the onboard satellite imager, to estimate the position and the attitude of the satellite. The sensor uses a camera model to take pictures of the Earth surface, a feature detector is ran on the image using scale invariant feature transform (SIFT) to identify and establish corospondance of features. A full state kinematic estimator using the extended Kalman Filter (EKF) based on the simultaneous localisation and mapping (SLAM) approach. The filter makes used of feature vectors and feature discriptors detected on the image. This is used to estimate attitude and position of the satellite.

An simulation environment in MATLAB is developed to propagate a satellite and determine the ground truth pose. Several traditional sensors like the star tracker and magnetometer and GPS to be able to compare the Earth Tracker and create the possiblity to fuse the sensors and determine the accuracy. Results show that the filter estimates the system states successfully. It is concluded that ...

### FUNCTIONS

$f$                          A function.

### VARIABLES

$x$                          A variable.

# INTRODUCTION

---

## 1.1 PROBLEM BACKGROUND

- Satellites are getting smaller - Because this leads to satellites having reduced costs and timelines - This is enabled by the miniaturisation of electronics
  - One of the big industries in satellites is remote sensing - Remote Sensing is the application where satellites are used to monitor the Earth - One of the applications is to take images of the Earth
    - This leads to the problem that high accuracy is needed to take images of the targets on the Earth's surface - COTS components which is mainly used on small satellites lack the accuracy needed - Magnetometers is too low of an accuracy - Star Trackers have the right accuracy, but is expensive

## 1.2 PROPOSED SOLUTION

- Proposed solution is to develop an estimation algorithm that can estimate the full state of the satellite - The Full State of a Satellite is its position in Space and its attitude or its orientation in space. - The satellite uses the imager itself to determine position and attitude. - This can lead to reduce costs as the satellite is using an instrument which is already onboard the satellite. - Utilising the components when it is idle - Observing the target directly

## 1.3 DOCUMENT OUTLINE

- Chapter 2: Will investigate previous sensors that is being used to determine Pose - Previous techniques estimating the pose - Some light touching on feature detection as this is crucial to the pose estimation system

- Chapter 3: Will introduce the modelling of the system - Rigid Body Kinematics - Position Kinematics - Attitude Kinematics - Kalman Filters - Extended Kalman Filters
- Chapter 4: Measurement Generation - Feature detection - PinHole Camera Model. - The Plant - The Plant Model - The Measurement Model
- Chapter 5: State estimation - The Extended Kalman Filter - Update Step - Prediction Step - Simulator
- Chapter 6 is results
- Chapter 7 is Conclusion - Future Work

### 3.1 INTRODUCTION

This project focuses on the pose estimation of a satellite using satellite images. This is essentially a localisation problem and requires a realistic description of the system. The aim of this chapter is to sufficiently define the problem and the proposed solution. Estimation algorithms are discussed and an estimator is chosen to solve the localisation problem. Further, attitude representations of a rigid body are introduced along with the dynamic and kinematic models used to describe a satellite in inertial space. Attention is given to quaternion attitude representations along with their propagation using angular rates.

### 3.2 PROBLEM DEFINITION

A satellite orbiting Earth in the Earth-Centered Inertial (ECI) reference frame performs Earth observation missions, continuously capturing high-resolution imagery of the planet's surface for scientific, commercial, or operational purposes. To fulfill mission objectives effectively, the satellite must provide not only high-quality imagery but also precise geographic information about observed areas. This requires accurate knowledge of the satellite's six-degree-of-freedom pose (three-dimensional position and three-dimensional attitude) relative to the ECI frame at the moment each image is captured.

Traditional satellite pose determination relies on external systems such as Global Navigation Satellite Systems (GNSS) and ground-based tracking networks. However, this thesis investigates an autonomous approach where the satellite performs "visual navigation" by identifying known ground features in its imagery and using these observations to determine its orbital state. The satellite essentially performs "reverse GPS" - instead of receiving position signals from space, it observes recognizable landmarks on Earth's surface and computes its pose from these visual references.

The core technical challenge lies in the transformation from raw imagery to precise pose estimates. This involves several interdependent problems: **(1) Feature Detection** - identifying which pixels in the imagery correspond to cataloged landmarks among millions of pixel observations; **(2) Geometric Inversion** - solving the complex inverse problem of determining six-dimensional pose from two-dimensional image projections of three-dimensional landmarks with known geographic coordinates; and **(3) Uncertainty Management** - handling measurement noise, feature detection errors, and dynamic orbital motion in real-time. This thesis assumes the availability of a pre-established catalog of ground features with precisely known geographic coordinates in the ECI frame. The feature matching problem - associating detected image features with specific catalog entries - is considered solved through prior knowledge of the observed terrain and existing geographic databases.

**Figure 3.1:** Satellite pose estimation concept showing orbital geometry, reference frames

This problem structure aligns with a simplified version of the Simultaneous Localization and Mapping (SLAM) framework. In this context, **localization** corresponds to determining the satellite's pose relative to the ECI frame using observations of cataloged features, while the **mapping** component is reduced to feature catalog utilization rather than creation. Since the geographic locations of observable features are assumed known a priori, the primary focus becomes the pose estimation problem given established feature correspondences.

The satellite's pose estimation system must account for the dynamic nature of orbital motion, the geometric relationship between the camera frame and satellite body frame, and the projection characteristics of the imaging system, while maintaining computational efficiency suitable for real-time onboard processing.

### 3.3 REFERENCE FRAME TRANSFORMATIONS

In this masters we are going to encounter a few different reference frames. To accurately create the measurement model we should have an understanding of all the different reference models and how to transform from one to another

#### 3.3.1 LATITUDE, LONGITUDE AND ALTITUDE

The latitude, longitude of a feature or the position of the satellite is denoted with the  $\mathcal{L}$ . The latitude of a feature is the position of how high or low it is above the equator, having a range of  $-90^\circ$  to  $90^\circ$ . The longitude is based on the Greenwich meridian, a longitude line that passes through the north- and south pole, it has a range of  $-180^\circ$  to  $180^\circ$ . The altitude is measured from the "WGS84" elliptical globe.

**Figure 3.2:** The Latitude, Longitude, Altitude reference frame in yellow with the ECEF reference frame in blue and the NED reference frame in green.

$$\mathbf{r}_{\mathcal{L}} = \begin{bmatrix} \lambda \\ \phi \\ h \end{bmatrix} \quad (3.1)$$

### 3.3.2 EARTH CENTERED EARTH FIXED

The Earth Centered Earth Fixed reference frame is represented by the  $\mathcal{F}$  and is very similar to the  $\mathcal{L}$  reference frame with the z-axis aligned with the northpole and the x-axis points at the crossing of the Prime Meridian and the Equator, where the y-axis completes the right hand rule. The x,y and z-axis is defined in kilometers. To convert from  $\mathcal{L}$  to  $\mathcal{F}$  is to use a "WGS84" transform. Where WGS84 stands for World Geodetic System 1984, which is the standard coordinate system used for Global Positioning System (GPS). The WGS84 transformation uses a reference ellipsoid that uses a semi-major axis of 6,378 km and a flattening of 1/298.2

$$\mathbf{A}_{\mathcal{L}}^{\mathcal{F}} = f(WGS84) \quad (3.2)$$

[Insert Figure Here](#)

### 3.3.3 EARTH CENTERED INERTIAL

The Earth Centered Inertial reference frame (ECI) referenced by  $\mathcal{I}$  shares a reference frame axis with the ECEF, but is rotated about the z-axis. This rotation is governed by the rotation speed of the earth  $\omega_e$  which is  $7.2921 \times 10^{-5}$  rad/s and time  $t$ .

$$\mathbf{A}_{\mathcal{F}}^{\mathcal{I}} = R(\omega_e t) = \begin{bmatrix} \cos(\omega_e t) & -\sin(\omega_e t) & 0 \\ \sin(\omega_e t) & \cos(\omega_e t) & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (3.3)$$

[Insert Figure Here](#)

### 3.3.4 ORBITAL REFERENCE FRAME

The orbital reference frame used is the Local Vertical Local Horizon (LVLH) denoted by  $\mathcal{O}$ . **The LVLH frame is a rotating, orbit-attached coordinate system commonly used in spacecraft dynamics. It moves with the satellite and is defined relative to its orbit around Earth.** The x-axis is the "Local Horizon" also called "along track" pointing forward it is tangent to the orbit and points in the direction of motion. The z-axis is the local vertical and is also called the Nadir direction, it points to the barycenter of the system, in this case the center of the Earth. The y-axis is called the cross track it completes the right handed system. It points out of the orbital plane, typically the angular momentum vector direction (normal to the orbit plane).

if  $\mathbf{r}$  is the position vector of the satellite and  $\mathbf{v}$  is the velocity vector of the satellite. The equation for the reference frame is:

$$\bar{z}_{\mathcal{O}} = -\frac{\mathbf{r}}{\|\mathbf{r}\|} \quad (3.4)$$

$$\bar{y}_{\mathcal{O}} = \frac{\mathbf{r} \times \mathbf{v}}{\|\mathbf{r} \times \mathbf{v}\|} \quad (3.5)$$

$$\bar{x}_{\mathcal{O}} = \bar{y}_{\mathcal{O}} \times \bar{z}_{\mathcal{O}} \quad (3.6)$$

For this reference frame there should also be a reference frame translation introduced. Which is done by substracing  $\mathbf{r}$  from the vector

$$\mathbf{f}_{\mathcal{O}} = \mathbf{A}_{\mathcal{I}}^{\mathcal{O}} \times (\mathbf{f}_{\mathcal{I}} - \mathbf{r}_{\mathcal{I}}) \quad (3.7)$$

Insert Figure Here. This is unfinished explain a bit more. Actually want to change it to the 4x4 transformation matrix

### 3.3.5 CAMERA REFERENCE FRAME

The camera reference frame denoted by  $\mathcal{C}$  and the body reference frame  $\mathcal{B}$  in this thesis is the same reference frame. This reference frame is transformed by using your standard quaternion rotation matrix.

$$\mathbf{f}_{\mathcal{C}} = \mathbf{A}_{\mathcal{O}}^{\mathcal{C}} \times \mathbf{f}_{\mathcal{O}} \quad (3.8)$$

### 3.3.6 IMAGE REFERENCE FRAME

### 3.3.7 EAST - NORTH - UP

## 3.4 RIGID BODY MECHANICS

### 3.4.1 KINEMATICS

The pose of a rigid body in a reference frame consists of the position and attitude of the body. The attitude, or orientation of a body-fixed reference frame to a known reference frame. This is usually represented by a rotation matrix, often referred to as a direction cosine Matrix (DCM). A rotation about a single coordinate axis is referred to as a coordinate rotation. A coordinate rotation about the x-,y- and z-axes with angles  $\phi$ ,  $\theta$  and  $\psi$ , of the body can be respectively describes as, [Willem de Jong p.23]

$$R_x(\phi) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(\phi) & \sin(\phi) \\ 0 & -\sin(\phi) & \cos(\phi) \end{bmatrix} \quad (3.9)$$

$$R_y(\theta) = \begin{bmatrix} \cos(\phi) & 0 & -\sin(\phi) \\ 0 & 1 & 0 \\ \sin(\phi) & 0 & \cos(\phi) \end{bmatrix} \quad (3.10)$$

$$R_z(\psi) = \begin{bmatrix} \cos(\phi) & \sin(\phi) & 0 \\ -\sin(\phi) & \cos(\phi) & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (3.11)$$

Any rotation in 3D space can be described by three coordinate rotations. The DCM describing the attitude of the target in the camera reference frame (CRF),  $\mathbf{A}_C^B$ , can be represented by three Euler angles. Each of the angles corresponds to one coordinate rotation. The order of the Euler 1-2-3 rotation, shown in Figure 3.5, is expressed as

$$\mathbf{A}_C^B = R_x(\phi)R_y(\theta)R_z(\psi) \quad (3.12)$$

$$\begin{bmatrix} a_{1,1} & a_{1,2} & a_{1,3} \\ a_{2,1} & a_{2,2} & a_{2,3} \\ a_{3,1} & a_{3,2} & a_{3,3} \end{bmatrix} \quad (3.13)$$

$$\begin{bmatrix} C\theta C\psi & C\theta S\psi & -S\theta \\ S\phi S\theta C\psi - C\phi S\psi & S\phi S\theta S\psi + C\phi C\psi & S\phi C\theta \\ C\phi S\theta C\psi + S\phi S\psi & C\phi S\theta S\psi - S\phi C\psi & C\phi C\theta \end{bmatrix} \quad (3.14)$$

Where S is the sine function and C is the cosine function. The Euler angles are calculated as follows

$$\phi = \arctan 2 \left( \frac{a_{2,3}}{a_{3,3}} \right) \quad (3.15)$$

$$\theta = \arctan 2 \left( \frac{-a_{1,3}}{\sqrt{a_{1,1}^2} + \sqrt{a_{1,2}^2}} \right) \quad (3.16)$$

$$\psi = \arctan 2 \left( \frac{a_{1,2}}{a_{1,1}} \right) \quad (3.17)$$

mathematical singularities occur when using Euler angles to represent large rotations. When both  $a_{1,1}$  and  $a_{1,2}$  in Equation 3.12 are zero, the expressions for  $\psi$  and  $\theta$  are undefined. This is known as *gimbal lock*, where the changes in the first and third Euler angles are indistinguishable when the second angle nears a critical value. Alternatively, the DCM can be described using quaternions, which do not have these singularities. The quaternion rotation is Figure ?? is expressed by the Euler axis  $\bar{\mathbf{e}} = [e_x, e_y, e_z]^T$  and the angle  $\theta$

$$\mathbf{q} = \begin{bmatrix} q_s \\ q_x \\ q_y \\ q_z \end{bmatrix} = \begin{bmatrix} \cos(\theta/2) \\ e_x \sin(\theta/2) \\ e_y \sin(\theta/2) \\ e_z \sin(\theta/2) \end{bmatrix} \quad (3.18)$$

**Figure 3.3:** Quaternion Rotation

The DCM as a function of Quaternion set is expressed as,

$$\mathbf{A}_C^B = \begin{bmatrix} q_s^2 + q_x^2 - q_y^2 - q_z^2 & 2(q_x q_y - q_s q_z) & 2(q_x q_z + q_s q_y) \\ 2(q_x q_y + q_s q_z) & q_s^2 - q_x^2 + q_y^2 - q_z^2 & 2(q_y q_z - q_s q_x) \\ 2(q_x q_z - q_s q_y) & 2(q_y q_z + q_s q_x) & q_s^2 - q_x^2 - q_y^2 + q_z^2 \end{bmatrix} \quad (3.19)$$

Using the normalisation constraint,  $q_s^2 + q_x^2 + q_y^2 + q_z^2 = 1$ , the DCM Simplifies to,

$$\mathbf{A}_C^B = \begin{bmatrix} 1 - 2(q_y^2 + q_z^2) & 2(q_x q_y - q_s q_z) & 2(q_x q_z + q_s q_y) \\ 2(q_x q_y + q_s q_z) & 1 - 2(q_x^2 + q_z^2) & 2(q_y q_z - q_s q_x) \\ 2(q_x q_z - q_s q_y) & 2(q_y q_z + q_s q_x) & 1 - 2(q_x^2 + q_y^2) \end{bmatrix} \quad (3.20)$$

The body-fixed angular rates of the satellite in CRF,  $\omega_C^B$ , is expressed as a function of quaternions by,

$$\omega_C^B = \begin{bmatrix} \omega_{bx} \\ \omega_{by} \\ \omega_{bz} \end{bmatrix} = 2 \begin{bmatrix} -q_x & q_s & -q_z & q_y \\ -q_3 & q_4 & q_1 & -q_2 \\ -q_4 & -q_3 & q_2 & q_s \end{bmatrix} \begin{bmatrix} \dot{q}_s \\ \dot{q}_x \\ \dot{q}_y \\ \dot{q}_z \end{bmatrix} \quad (3.21)$$

Inversly the quaternion rates as a function of the body rates are,

$$\begin{bmatrix} \dot{q}_s \\ \dot{q}_x \\ \dot{q}_y \\ \dot{q}_z \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 0 & -\omega_{bx} & -\omega_{by} & -\omega_{bz} \\ \omega_{bx} & 0 & \omega_{bz} & -\omega_{by} \\ \omega_{by} & -\omega_{bz} & 0 & \omega_{bx} \\ \omega_{bz} & \omega_{by} & -\omega_{bx} & 0 \end{bmatrix} \begin{bmatrix} q_s \\ q_x \\ q_y \\ q_z \end{bmatrix} \quad (3.22)$$

Quaternions will be used throughout this thesis for attitude representations. Quaternions do not have ambiguity regarding the order of rotations and the rotation is around a well-defined axis. The sin and cosine elements of the rotation matrix are already encoded in the quaternion form of the DCM. Therefore, only one matrix operation is required for attitude transforms, where Euler angles require three.

### 3.4.2 DYNAMICS

The rotational dynamics of a rigid body satellite can be described using the Newton-Euler equations, which are applicable to all rigid inertial bodies [? ]. The angular momentum of the satellite is expressed as:

$$\dot{\mathbf{H}} = \frac{d\mathbf{H}}{dt} = \mathbf{I}\dot{\boldsymbol{\omega}} \quad (3.23)$$

where  $\mathbf{H}$  represents the angular momentum vector and  $\mathbf{I}$  is the diagonalized moment of inertia tensor about the satellite's principal axes. In the absence of external torques, the rotational kinematics of a rigid satellite about its center of mass can be described by Euler's rotational equations:

$$I_{xx}\dot{\omega}_x = \omega_y\omega_z(I_{yy} - I_{zz}) \quad (3.24)$$

$$I_{yy}\dot{\omega}_y = \omega_x\omega_z(I_{zz} - I_{xx}) \quad (3.25)$$

$$I_{zz}\dot{\omega}_z = \omega_x\omega_y(I_{xx} - I_{yy}) \quad (3.26)$$

where  $I_{xx}$ ,  $I_{yy}$ , and  $I_{zz}$  are the principal moments of inertia, which remain constant and depend on the satellite's mass distribution and geometric configuration.

The stability characteristics of the satellite's rotational motion are governed by its mass distribution. According to Marsden and Ratiu [? ], rotation about the major and minor principal axes is inherently stable, while rotation about the intermediate axis exhibits unstable behavior. Under constant energy conditions, any initial rotation about the intermediate axis will gradually redistribute energy to the major and minor axes through nutation effects.

For the translational dynamics, Newton's second law governs the linear motion of the satellite with mass  $m$ . The discrete-time position and velocity propagation equations are:

$$\mathbf{r}_t = \mathbf{r}_{t-1} + \mathbf{v}_t \Delta t + \frac{1}{2m} \mathbf{F}(t) \Delta t^2 \quad (3.27)$$

$$\mathbf{v}_t = \mathbf{v}_{t-1} + \frac{1}{m} \mathbf{F}(t) \Delta t \quad (3.28)$$

where  $\mathbf{F}(t)$  represents the net external force acting on the satellite. For the orbital environment considered in this work, where external perturbations are negligible compared to gravitational forces, and given that precise mass properties may not be available, the translational motion can be approximated using kinematic models where the current velocity depends primarily on the previous velocity state.

To propagate the quaternion representing the satellite's attitude over time, the quaternion derivative must first be computed. The time derivative of the quaternion  $\mathbf{q}_{B/I}$ , which describes the rotation from the inertial frame to the body frame, is calculated using quaternion multiplication with the angular velocity vector:

$$\dot{\mathbf{q}}_{B/I} = \frac{1}{2} (\mathbf{q}_{B/I} \otimes \boldsymbol{\omega}) \quad (3.29)$$

where  $\boldsymbol{\omega} = [\omega_x, \omega_y, \omega_z]^T$  is the angular velocity vector expressed in the body frame. Expanding this quaternion multiplication yields:

$$\dot{\mathbf{q}}_{B/I} = \frac{1}{2} \begin{bmatrix} q_{B/I,0}\omega_x - q_{B/I,3}\omega_y + q_{B/I,2}\omega_z \\ q_{B/I,3}\omega_x + q_{B/I,0}\omega_y - q_{B/I,1}\omega_z \\ -q_{B/I,2}\omega_x + q_{B/I,1}\omega_y + q_{B/I,0}\omega_z \\ -q_{B/I,1}\omega_x - q_{B/I,2}\omega_y - q_{B/I,3}\omega_z \end{bmatrix} \quad (3.30)$$

where  $q_{B/I,0}$ ,  $q_{B/I,1}$ ,  $q_{B/I,2}$ , and  $q_{B/I,3}$  are the scalar and vector components of the quaternion, respectively.

The quaternion integration is performed using a simple Euler integration scheme. First, the quaternion is propagated forward in time using:

$$\bar{\mathbf{q}}_{B/I}(t + \Delta t) = \mathbf{q}_{B/I}(t) + \dot{\mathbf{q}}_{B/I} \Delta t \quad (3.31)$$

where  $\bar{\mathbf{q}}_{B/I}(t + \Delta t)$  represents the unnormalized quaternion after integration. Since quaternion integration may introduce numerical errors that violate the unit quaternion constraint, the result must be renormalized:

$$\mathbf{q}_{B/I}(t + \Delta t) = \frac{\bar{\mathbf{q}}_{B/I}(t + \Delta t)}{\|\bar{\mathbf{q}}_{B/I}(t + \Delta t)\|} \quad (3.32)$$

This normalization step ensures that the quaternion maintains its unit magnitude, preserving the validity of the attitude representation.

## 4.1 INTRODUCTION

## 4.2 PINHOLE CAMERA MODEL

The Ideal Pinhole Camera model can be seen as a dark box with a hole on the side of the box, this is called the optical centre. If a point passes through the optical centre, it will be reflected on the inside of the box. The two sides of the box being defined as the focal length  $f$  and the projection side of the box is defined as the projection of the plane.
